

# **Limitations of Private-Key Cryptography**

- traditional **private/secret/single key** cryptography uses **one key**
  - ❖ shared by both sender and receiver
  - ❖ if this key is disclosed communications are compromised - KDC
- does not protect sender from receiver
  - ❖ forging a message &
  - ❖ claiming as sent by sender - DI

# Public-Key Cryptography

- probably most significant advance in the 3000 year history of cryptography
- uses **two** keys – a public & a private key
- **asymmetric**
- uses clever application of number theoretic concepts to function
- complements rather than replaces private key cryptography

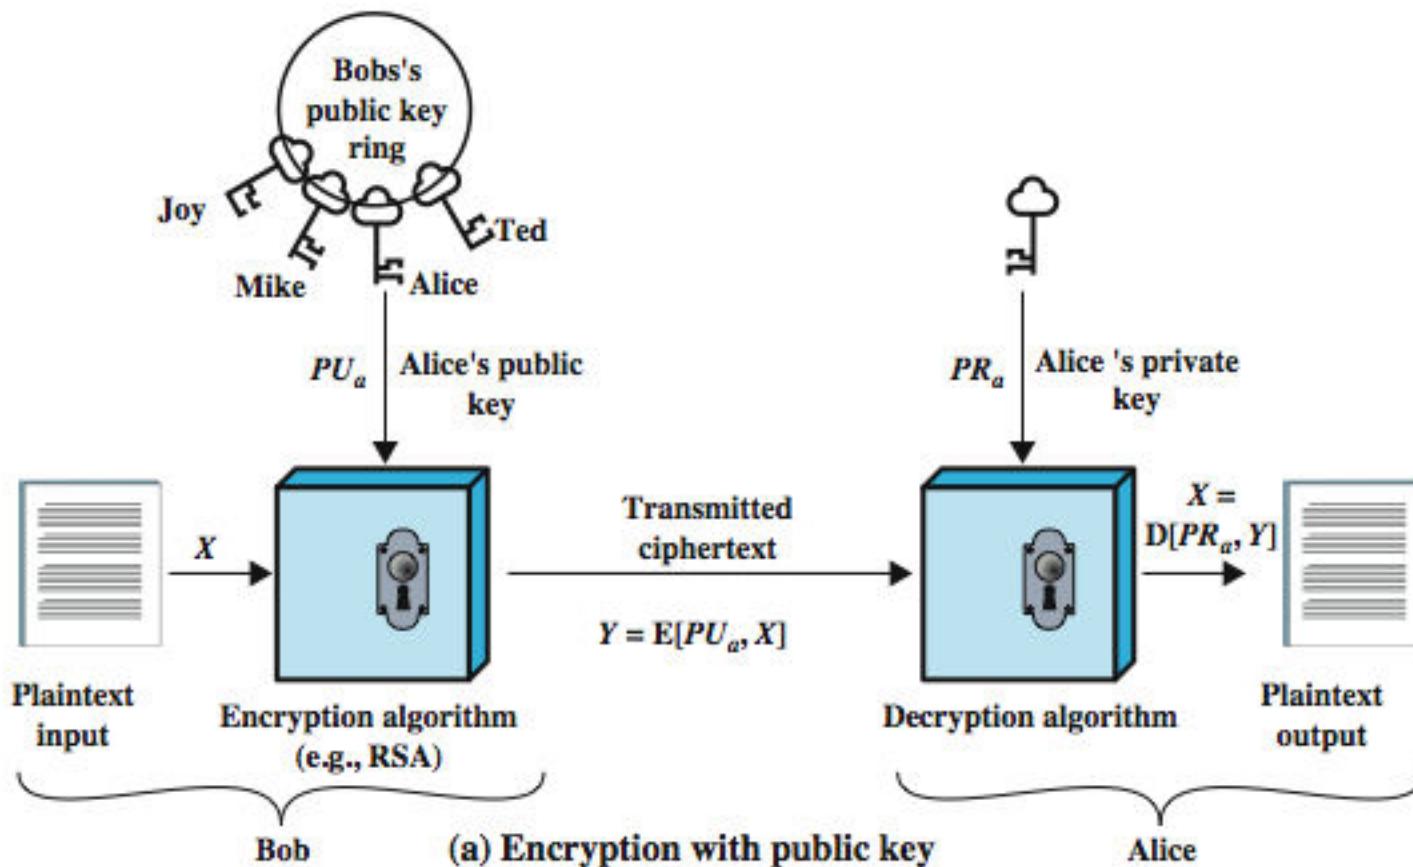

# Why Public-Key Cryptography?

- developed to address two key issues:
  - **key distribution** – how to have secure communications in general without having to trust a KDC with your key
  - **digital signatures** – how to verify a message comes intact from the claimed sender
- public invention due to Whitfield Diffie & Martin Hellman at Stanford Univ in 1976
  - known earlier in classified community

# Public-Key Cryptography

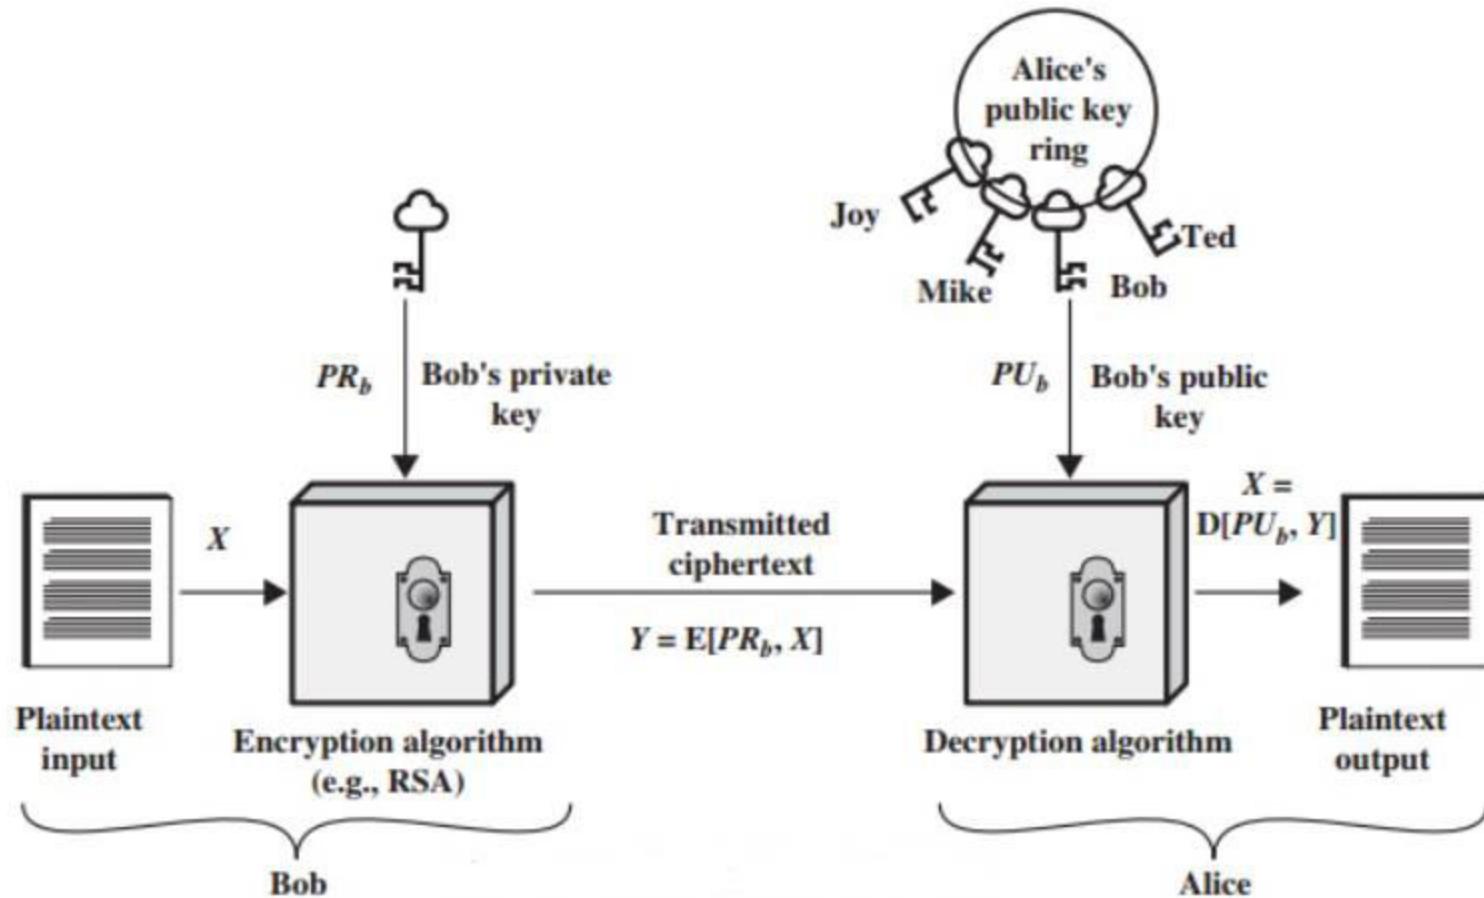

- **public-key/two-key/asymmetric** cryptography involves the use of **two keys**:
  - a **public-key**, which may be known by anybody, and can be used to **encrypt messages**, and **verify signatures**
  - a related **private-key**, known only to the recipient, used to **decrypt messages**, and **sign** (create) **signatures**
- **infeasible to determine private key from public**
- **is asymmetric** because
  - those who encrypt messages or verify signatures **cannot** decrypt messages or create signatures

# Symmetric vs Public-Key

## Symmetric

1. Based on sharing secrecy

Key

2. Symbols are permuted

chars, bits

3. In an n people env,

$n(n-1)/2$  keys

4. Faster hence preferred  
for larger msgs

5. Primitive applications

## Asymmetric

Personal secrecy

Authentication, DiS

Numbers are manipulated

mathematical fns

n shared keys

Slower than Symmetric

Authentication, DiS

# Public-Key Cryptosystems

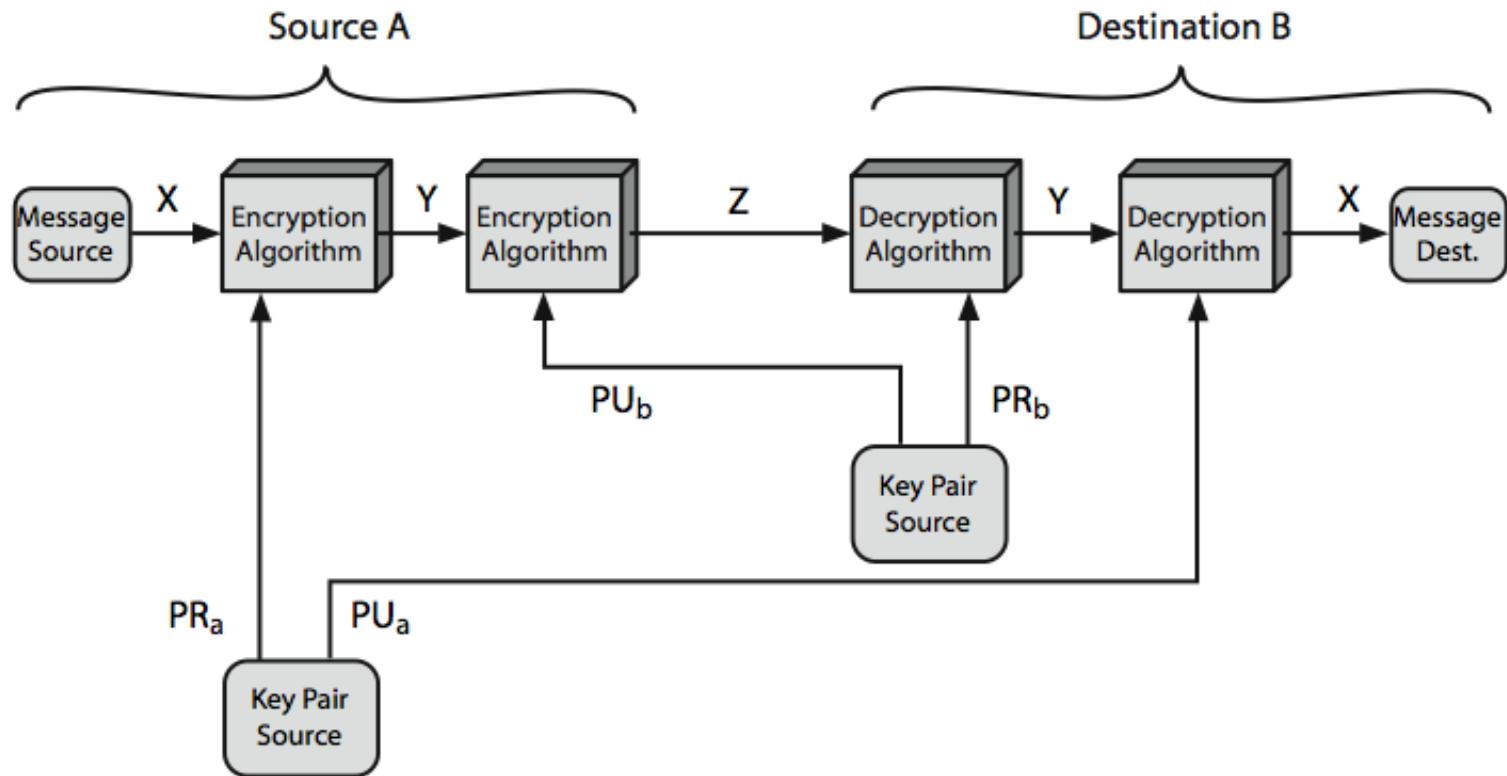

Figure. Encryption with Private Key-  $PR_a$  - Authn and DI

# Public-Key Applications

- can classify uses into 3 categories:
  - encryption/decryption (provide secrecy)
  - digital signatures (provide authentication)
  - key exchange (of session keys)
- some algorithms are suitable for all uses, others are specific to one

Algorithm	Encryption/Decryption	Digital Signature	Key Exchange
RSA	Yes	Yes	Yes
Elliptic Curve	Yes	Yes	Yes
Diffie-Hellman	No	No	Yes
DSS	No	Yes	No

# Public-Key Requirements

- Public-Key algorithms rely on two keys where:
  - it is computationally infeasible to find decryption key knowing only algorithm & encryption key
  - it is computationally easy to en/decrypt messages when the relevant (en/decrypt) key is known
  - either of the two related keys can be used for encryption, with the other used for decryption (for some algorithms)
- these are formidable requirements which only a few algorithms have satisfied

# Public-Key Requirements

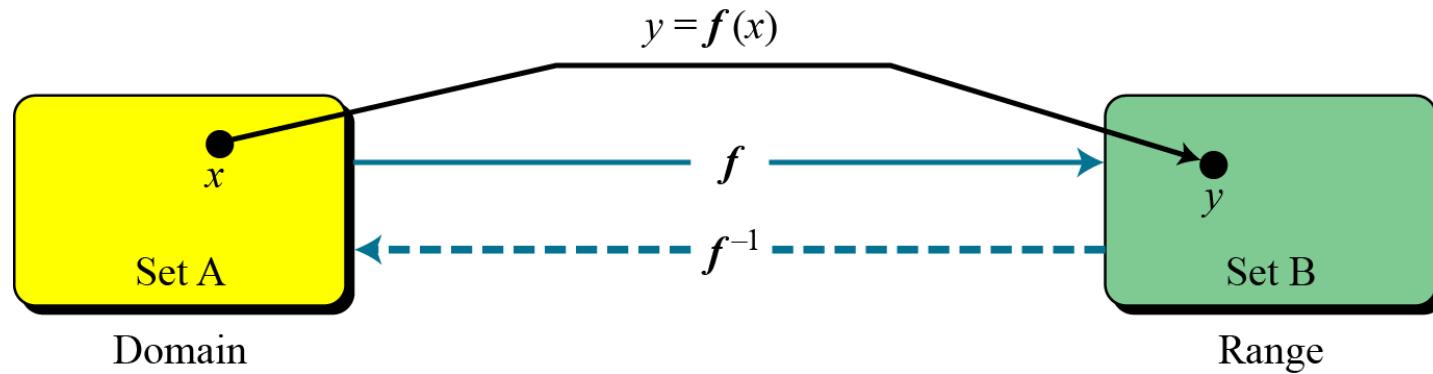

- need a trapdoor one-way function
- one-way function has
  - $Y = f(X)$  easy
  - $X = f^{-1}(Y)$  infeasible
- a trap-door one-way function has
  - $Y = f_k(X)$  easy, if  $k$  and  $X$  are known
  - $X = f_k^{-1}(Y)$  easy, if  $k$  and  $Y$  are known
  - $X = f_k^{-1}(Y)$  infeasible, if  $Y$  known but  $k$  not known
- a practical public-key scheme depends on a suitable trap-door one-way function

# Trapdoor One-Way Function

*The main idea behind asymmetric-key cryptography is the concept of the trapdoor one-way function.*

## Functions

### Figure

## *One-Way Function (OWF)*

1. *f is easy to compute.  $y=f(x)$*
2.  *$f^{-1}$  is difficult to compute.*  
 $x = f^{-1}(y)$

## *Trapdoor One-Way Function (TOWF)*

3. *Given y and a trapdoor, x can be computed easily.*

# Security of Public Key Schemes

- like private key schemes brute force **exhaustive search** attack is always theoretically possible
- but **keys used are too large (>512bits)**
- security relies on a **large enough** difference in difficulty between **easy** (en/decrypt) and **hard** (cryptanalyst) problems
- more generally the **hard** problem is known, but is made **hard enough** to be impractical to break
- requires the use of **very large numbers**
- hence is **slow** compared to private key schemes

# RSA

- by Rivest, Shamir & Adleman of MIT in 1977
- best known & widely used public-key scheme
- based on exponentiation in a finite (Galois) field over integers modulo a prime
  - nb. exponentiation takes  $O((\log n)^3)$  operations (easy)
- uses large integers (eg. 1024 bits)
- security due to cost of factoring large numbers
  - nb. factorization takes  $O(e^{\log n \log \log n})$  operations (hard)

# RSA En/decryption

- to encrypt a message  $M$  the sender:
  - obtains **public key** of recipient  $PU = \{e, n\}$
  - computes:  $C = M^e \text{ mod } n$ , where  $0 \leq M < n$
- to decrypt the ciphertext  $C$  the owner:
  - uses their **private key**  $PR = \{d, n\}$
  - computes:  $M = C^d \text{ mod } n$
- note that the message  $M$  must be smaller than the modulus  $n$  (block if needed)

# RSA Key Setup

- each user generates a public/private key pair by:
- selecting two large primes at random:  $p, q$
- computes their system modulus  $n=p \cdot q$ 
  - note  $\phi(n) = (p-1)(q-1)$
- selecting at random the encryption key  $e$ 
  - where  $1 < e < \phi(n)$ ,  $\gcd(e, \phi(n)) = 1$
- solve following equation to find decryption key  $d$ 
  - $e \cdot d \equiv 1 \pmod{\phi(n)}$  and  $0 \leq d \leq n$
- publish their public encryption key:  $PU=\{e,n\}$
- keep secret private decryption key:  $PR=\{d,n\}$

# Why RSA Works

- because of Euler's Theorem:
  - $a^{\phi(n)} \text{mod } n = 1$  where  $\gcd(a, n) = 1$
- in RSA have:
  - $n = p \cdot q$
  - $\phi(n) = (p-1)(q-1)$
  - carefully chose  $e$  &  $d$  to be inverses mod  $\phi(n)$
  - hence  $e \cdot d = 1 + k \cdot \phi(n)$  for some  $k$
- hence :
  - $$C^d = M^e \cdot d = M^{1+k \cdot \phi(n)} = M^1 \cdot (M^{\phi(n)})^k$$
  - $$= M^1 \cdot (1)^k = M^1 = M \text{ mod } n$$

# RSA Example - Key Setup

1. Select primes:  $p=17$  &  $q=11$
2. Calculate  $n$
3. Calculate  $\phi(n)$
4. Select  $e$

# RSA Example - Key Setup

1. Select primes:  $p=17$  &  $q=11$
2. Calculate  $n = pq = 17 \times 11 = 187$
3. Calculate  $\phi(n) = (p-1)(q-1) = 16 \times 10 = 160$
4. Select  $e$ :  $\gcd(e, 160) = 1$ ; choose  $e=7$
5. Determine  $d$ :
6. Publish public key PU
7. Keep secret private key PR

# RSA Example - Key Setup

1. Select primes:  $p=17$  &  $q=11$
2. Calculate  $n = pq = 17 \times 11 = 187$
3. Calculate  $\phi(n) = (p-1)(q-1) = 16 \times 10 = 160$
4. Select e:  $\gcd(e, 160) = 1$ ; choose  $e=7$
5. Determine d:  $de \equiv 1 \pmod{160}$  and  $d < 160$   
Value is  $d=23$  since  $23 \times 7 = 161 = 10 \times 160 + 1$
6. Publish public key PU={7, 187}
7. Keep secret private key PR={23, 187}

# RSA Example - En/Decryption

- sample RSA encryption/decryption is:
- given message  $M = 88$  (nb.  $88 < 187$ )
- encryption:

$C =$

decryption:

$M =$

# RSA Example - En/Decryption

- sample RSA encryption/decryption is:
- given message  $M = 88$  (nb.  $88 < 187$ )
- encryption:

$$C = 88^7 \bmod 187 = 11$$

- decryption:

$$M =$$

# RSA Example - En/Decryption

- sample RSA encryption/decryption is:
- given message  $M = 88$  (nb.  $88 < 187$ )
- encryption:

$$C = 88^7 \bmod 187 = 11$$

- decryption:
- $$M = 11^{23} \bmod 187 = 88$$

# Exponentiation

- can use the **Square and Multiply Algorithm**
- a **fast, efficient algorithm for exponentiation**
- concept is based on repeatedly **squaring base**
- and multiplying in the ones that are needed to compute the result
- look at binary representation of exponent
- only takes  $O(\log_2 n)$  multiples for number n
  - eg.  $7^5 = 7^4 \cdot 7^1 = 3 \cdot 7 = 10 \bmod 11$
  - eg.  $3^{129} = 3^{128} \cdot 3^1 = 5 \cdot 3 = 4 \bmod 11$

# Exponentiation

```
c = 0; f = 1
for i = k downto 0
    do c = 2 x c
        f = (f x f) mod n
    if bi == 1 then
        c = c + 1
        f = (f x a) mod n
return f
```

# Efficient Encryption

- encryption uses **exponentiation** to power e
- hence if e small, this will be faster
  - often choose  $e=65537$  ( $2^{16}-1$ )
  - also see choices of  $e=3$  or  $e=17$
- but if e too small (eg  $e=3$ ) can attack
  - using Chinese remainder theorem & 3 messages with different modulii
- if e fixed must ensure  $\gcd(e, \phi(n)) = 1$ 
  - ie reject any p or q not relatively prime to e

# **Efficient Decryption**

- decryption uses **exponentiation** to power d
  - this is likely large, insecure if not
- can use the Chinese Remainder Theorem (CRT) to compute mod p & q separately. then combine to get desired answer
  - approx 4 times faster than doing directly
- only owner of private key who knows values of p & q can use this technique

# RSA Key Generation

- users of RSA must:
  - determine two primes at random - p, q
  - select either e or d and compute the other
- primes p, q must not be easily derived from modulus  $n=p \cdot q$ 
  - means must be sufficiently large
  - typically guess and use probabilistic test
- exponents e, d are inverses, so use Inverse algorithm to compute the other

# RSA Security

- possible approaches to attacking RSA are:
  - brute force key search - infeasible given size of numbers
  - mathematical attacks - based on difficulty of computing  $\phi(n)$ , by factoring modulus n
  - timing attacks - on running of decryption
  - chosen ciphertext attacks - given properties of RSA

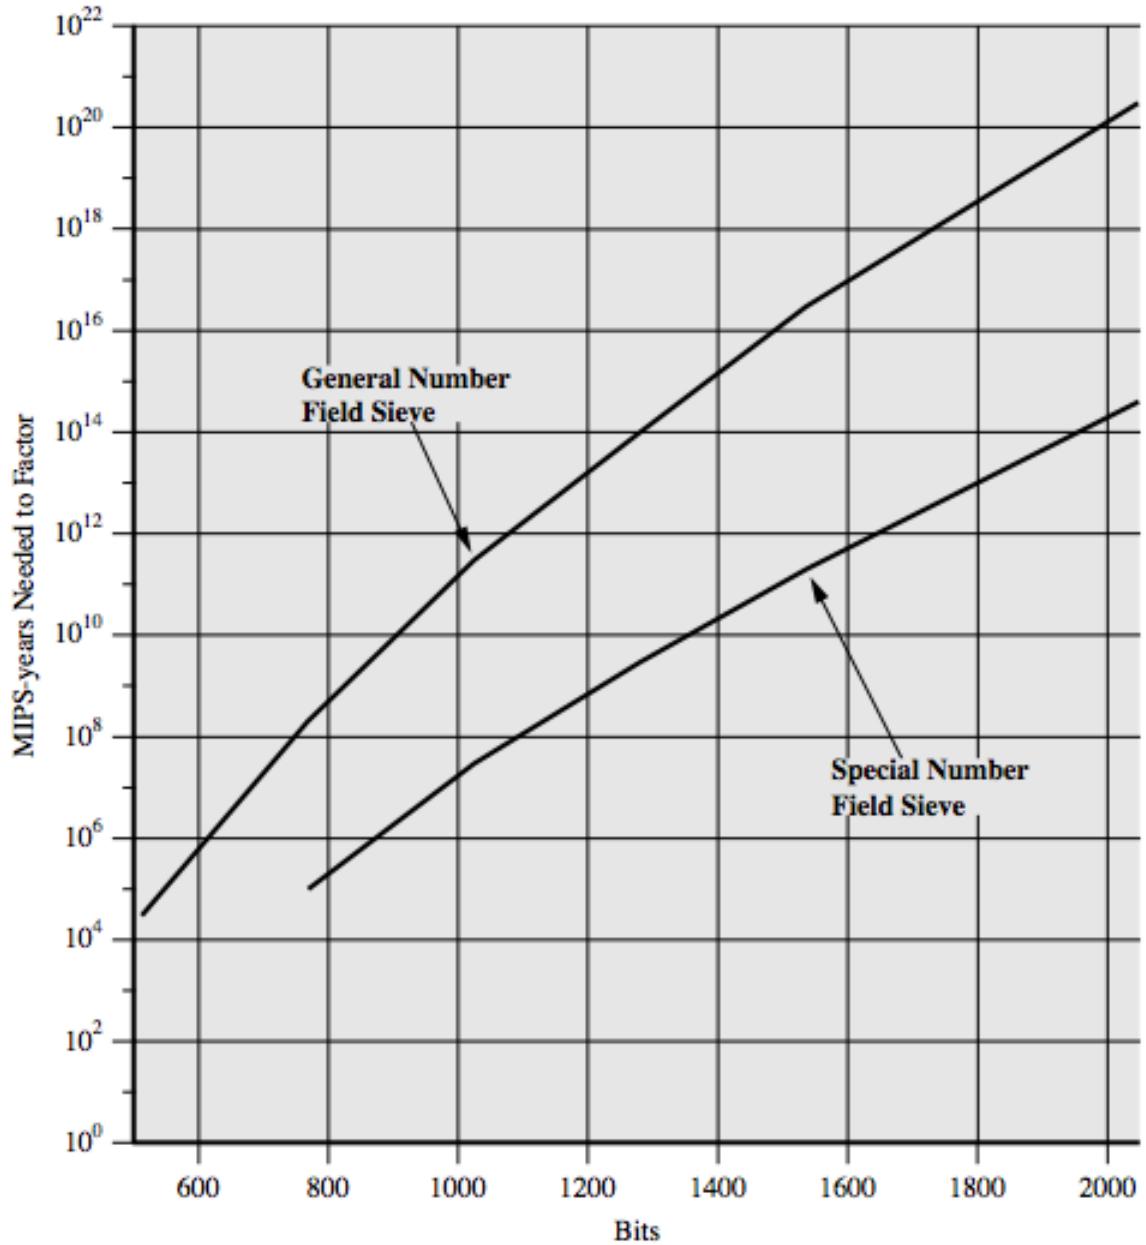

# Factoring Problem

- mathematical approach takes 3 forms:
  - factor  $n=p \cdot q$ , hence compute  $\phi(n)$  and then  $d$
  - determine  $\phi(n)$  directly and compute  $d$
  - find  $d$  directly
- currently believe all equivalent to factoring
  - have seen slow improvements over the years
    - as of May-05 best is 200 decimal digits (663) bit with LS
  - biggest improvement comes from improved algorithm
    - cf QS to GHFS to LS
  - currently assume 1024-2048 bit RSA is secure
    - ensure  $p, q$  of similar size and matching other constraints

# Progress in Factoring

Number of Decimal Digits	Approximate Number of Bits	Date Achieved	MIPS-years	Algorithm

# Progress in Factoring

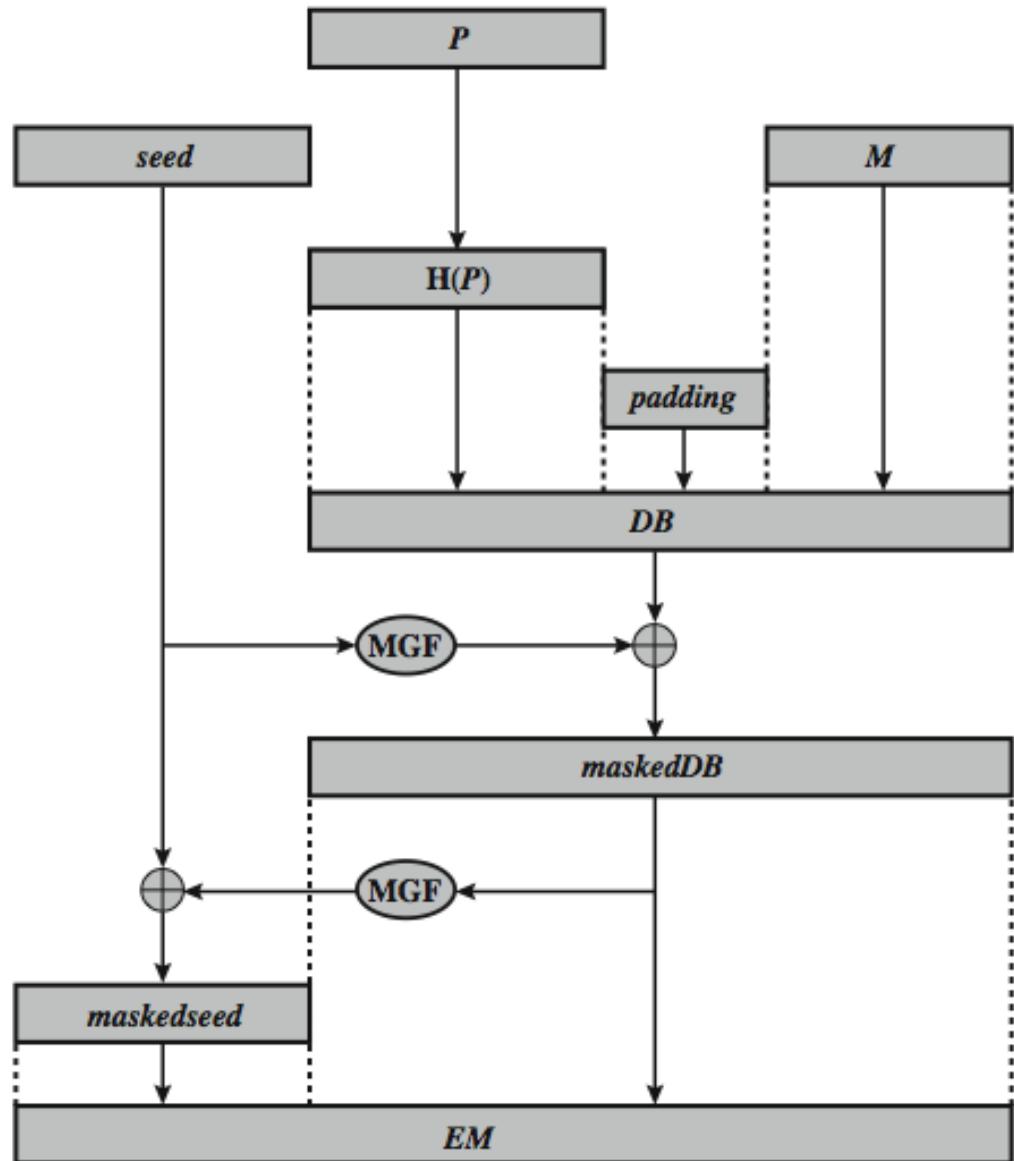

# Timing Attacks

- developed by Paul Kocher in mid-1990's
- exploit timing variations in operations
  - eg. multiplying by small vs large number
  - or IF's varying which instructions executed
- infer operand size based on time taken
- RSA exploits time taken in exponentiation
- countermeasures
  - use constant exponentiation time
  - add random delays
  - blind values used in calculations

# Chosen Ciphertext Attacks

- RSA is vulnerable to a Chosen Ciphertext Attack (CCA)
- attackers chooses ciphertexts & gets decrypted plaintext back
- choose ciphertext to exploit properties of RSA to provide info to help cryptanalysis
- can counter with random pad of plaintext
- or use Optimal Asymmetric Encryption Padding (OAEP)

# Optimal Asymmetric Encryption Padding (OASP)

$P$  = encoding parameters

$M$  = message to be encoded

$H$  = hash function

$DB$  = data block

$MGF$  = mask generating function

$EM$  = encoded message

# **Summary**

- have considered:
  - principles of public-key cryptography
  - RSA algorithm, implementation, security
